Residue triplets: datasets script

Ordered sequence $X = (a_1, \ldots, a_L)$
Process one residue a_i at a time

↓

Per-residue molecule object M_i
`Chem.MolFromSequence(`a_i`)`

↓

$d_i = (\mathrm{MolWt}(M_i),\ \mathrm{MolLogP}(M_i),\ \mathrm{TPSA}(M_i))$
Each component rounded to two decimals

↓

Aligned features $D = (d_1, \ldots, d_L)$
Position i matches residue a_i; loader zero-pads to 48

SMILES describes the intermediate representation in the historical manuscript; this active script does not serialize SMILES.

Boundary. The alternate tasks script uses a different triplet. The historical script/version and residue-to-number mapping remain unknown; no chemical values are inferred here.
