AMP candidate: GO / NO_GO

12 October 2026

Decision: GO for complete substantive review; NO_GO for submission.

Candidate format. Bioinformatics Original Paper, using its permitted format-free first-submission layout. This is not a production-template compliance claim. Communications Biology is less aligned with the current absence of a demonstrated biological advance. No acceptance probability is estimated.

Strongest supported claim. In one frozen development setting, CE21 improves reconstruction and low-order generation distances relative to same-capacity MSE21, but its sampling pipeline does not beat the executed terminal LSTM on the six specified sequence-distribution distances. This is a bounded implementation case, not a novel model or general benchmark. Prior literature already separates reconstruction from generation.

Submission blocker	Evidence required to close it
Scientific scope	Establish a distinct and useful contribution relative to existing AMP evaluations; support any broader claim with independent confirmation and adequate comparison. Current single-seed, reused-dev results do not do so.
Reproducibility	Resolve a usable data/code/weight release and access arrangement, baseline adequacy and the interrupted-attempt provenance. Local hashes are not public availability or fresh reproduction.
Historical biology	Any application-efficacy claim requires model-to-selection-to-sample linkage and verified MIC rules, N meaning, repeat identities and assay aggregation. The present manuscript makes no such claim.
Human responsibility	Confirm authors, affiliations, contributions, funding, conflicts, overlap with related work, complete AI-use disclosure and actual final human approval. These cannot be supplied by AI technical checks.

Completed review deliverables. Main manuscript, combined supplement with all 27 historical rows, deterministic figure/source data, verified bibliography, cover-letter draft, official-guideline evidence and independent review records. No result section is replaced with a promised future experiment. Unresolved author declarations are visibly marked.

Boundaries preserved. No new training, no new sampling, no reserved-test access, no modification of v6-r3 or earlier research snapshots, no external upload or journal submission. Biological activity is not inferred from sequence statistics. Publication decisions remain with human authors and the journal.
